But the most fundamental question remains unanswered; viz., has the egg after its first cleavage divided its material into qualitatively different parts (i.e. has the material of the right side of the body been separated qualitatively from that of the left side), or are the first-formed blastomeres still undifferentiated, and their subsequent fate dependent on the relative position they bear to each other as a part of a whole? Houx tried to answer this question by the following ingenious experiment. Roux's Experiment Of Killing One Of The First Two Blastomeres As soon as the first furrow had passed through the egg, one of the resulting blastomeres was pierced with a hot needle. In order to carry out the experiment successfully, certain precautions must be taken. The eggs as soon as removed from the uterus are scattered over a glass plate (under water) so that they lie singly. Then water containing spermatozoa is added. After ten minutes this water, clouded by the spermatozoa, is poured off and fresh water is added. When the first furrow in the eggs appears, the water is again poured off. Each egg is held by a pair of forceps and then pierced by a hot needle. The needle is carefully sharpened, and is resharpened after each egg is operated upon. It is best to pierce the blastomere in the black hemisphere near the first cleavage-plane. The needle passes through about a half (or more) of the blastomere. When the needle is withdrawn, a greater or less amount of the contents of the blastomere protrudes where the blastomere has been injured. The egg after

operation is returned to the water. It is necessary...
